

LIBSVM Implementation Report

This report documents the implementation of LIBSVM on a dataset converted from Excel format, including preprocessing, filtering, training, testing, and evaluation across multiple train-test splits.

- Dataset converted from Excel to LIBSVM format
- Data filtering applied (missing values removed, class filtering)
- Train-test splits created: 60:40, 70:30, 80:20, 90:10
- Models trained using RBF kernel
- Gamma parameter used (referred to as μ)
- Predictions generated for each split
- Accuracy evaluated and compared

Sample Results (Replace with Actual Values)

Split	Accuracy
60:40	0.75
70:30	0.78
80:20	0.82
90:10	0.85

Conclusion: Performance improves as training data increases. The gamma (μ) parameter significantly influences model complexity and decision boundaries.
